CS4102 Algorithms

Fall 2018

Warm up

Why is an algorithm's space complexity (how much memory it uses) important?

Why might a memory-intensive algorithm be a "bad" one?

Why lots of memory is “bad”

Today’s Keywords

- Greedy Algorithms
- Choice Function
- Cache Replacement
- Hardware & Algorithms

CLRS Readings

- Chapter 16

Homeworks

- HW6 Due Friday Nov 9 @11pm
  - Written (use latex)
  - DP and Greedy

Caching Problem

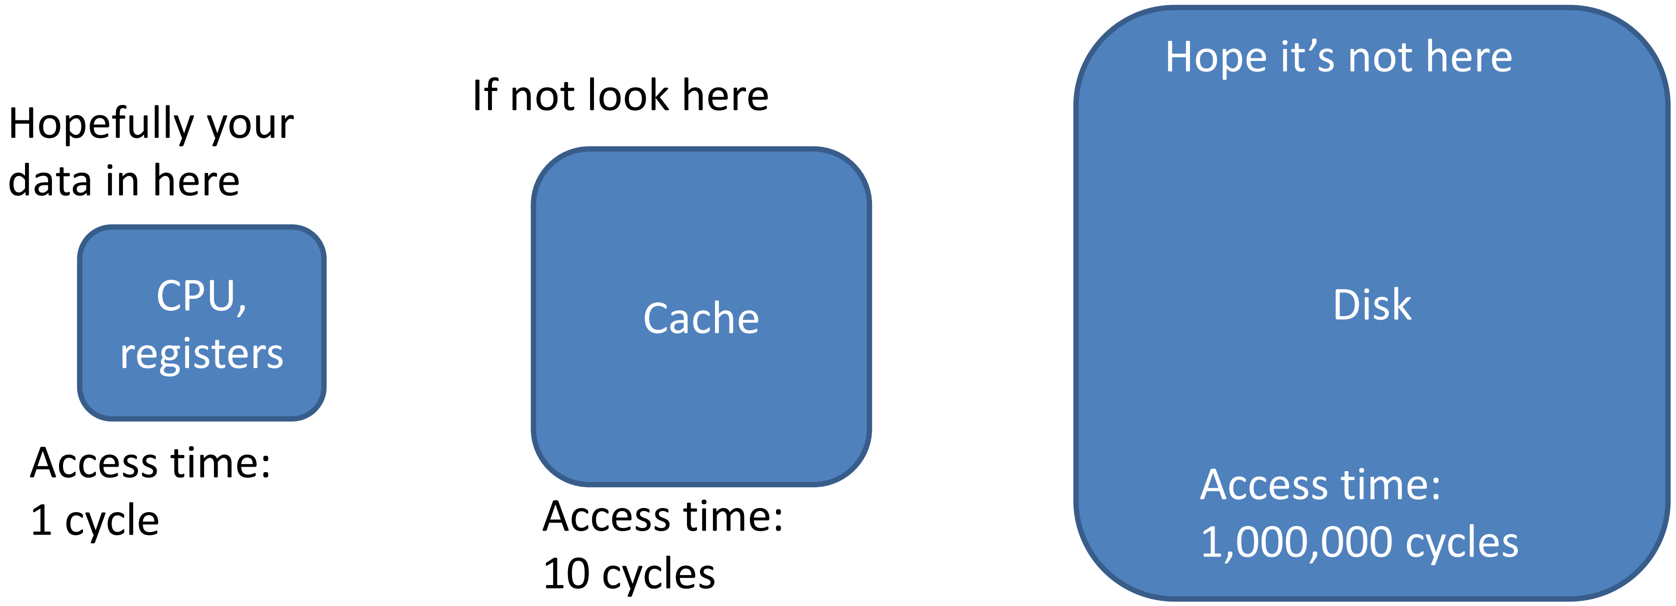
- Why is using too much memory a bad thing?

Von Neumann Bottleneck

- Named for John von Neumann
- Inventor of modern computer architecture
- Other notable influences include:
  - Mathematics
  - Physics
  - Economics
  - Computer Science

Von Neumann Bottleneck

- Reading from memory is VERY slow
- Big memory = slow memory
- Solution: hierarchical memory
- Takeaway for Algorithms: Memory is time, more memory is a lot more time



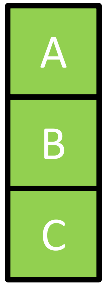
Caching Problem

- Cache misses are very expensive
- When we load something new into cache, we must eliminate something already there
- We want the best cache “schedule” to minimize the number of misses

Caching Problem Definition

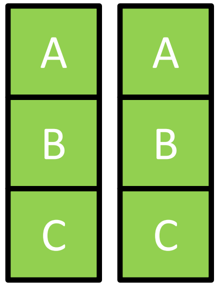
- Input:
  - k = size of the cache
  - $M = [m_1, m_2, \ldots m_n]$ = memory access pattern
- Output:
  - "schedule" for the cache (list of items in the cache at each time) which minimizes cache fetches

Example



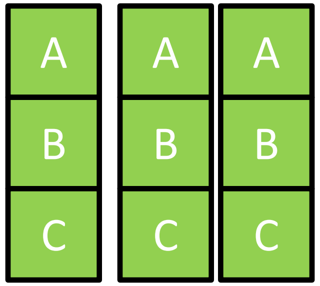
A B C D A D E A D B A E C E A

Example



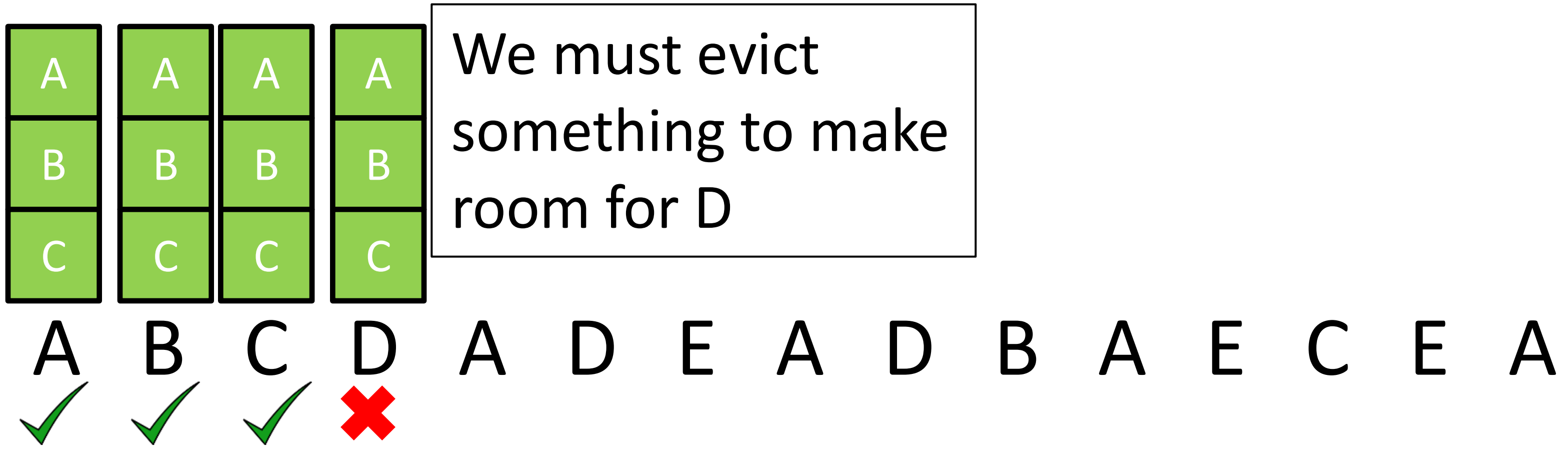
A B C D A D E A D B A E C E A

Example



A B C D A D E A D B A E C E A

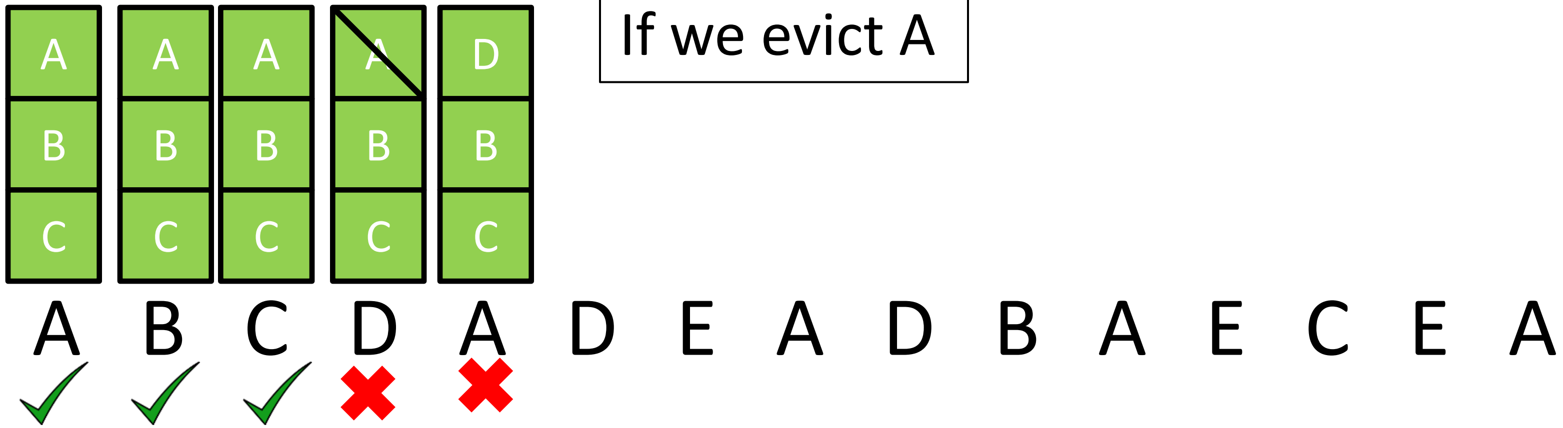
Example



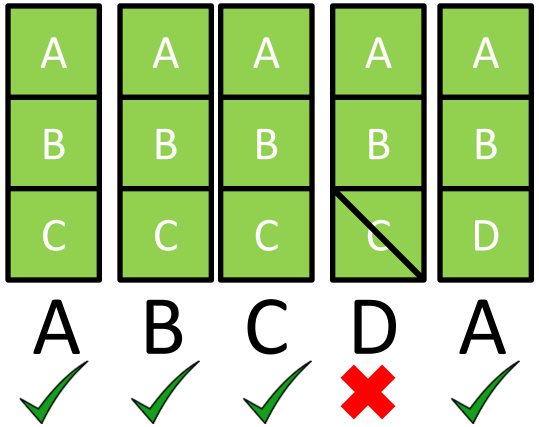
A
B
C
We must evict something to make room for D
A B C D A D E A D B A E C E A

Example

If we evict A



Example

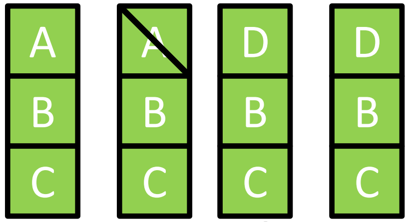


If we evict C

A B C D A D E A D B A E C E A

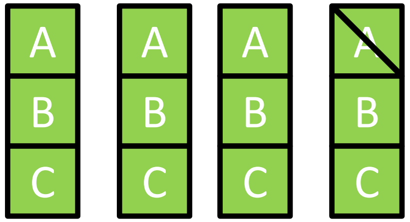
Our Problem vs Reality

- Assuming we know the entire access pattern
- Cache is Fully Associative
- Counting # of fetches (not necessarily misses)
- “Reduced” Schedule: Address only loaded on the cycle it’s required
  - Reduced == Unreduced (by number of misses)



Unreduced

A B C D A D E A D B A E C E A



Reduced

Leaving A in longer does not save fetches

A B C D A D E A D B A E C E A

Greedy Algorithms

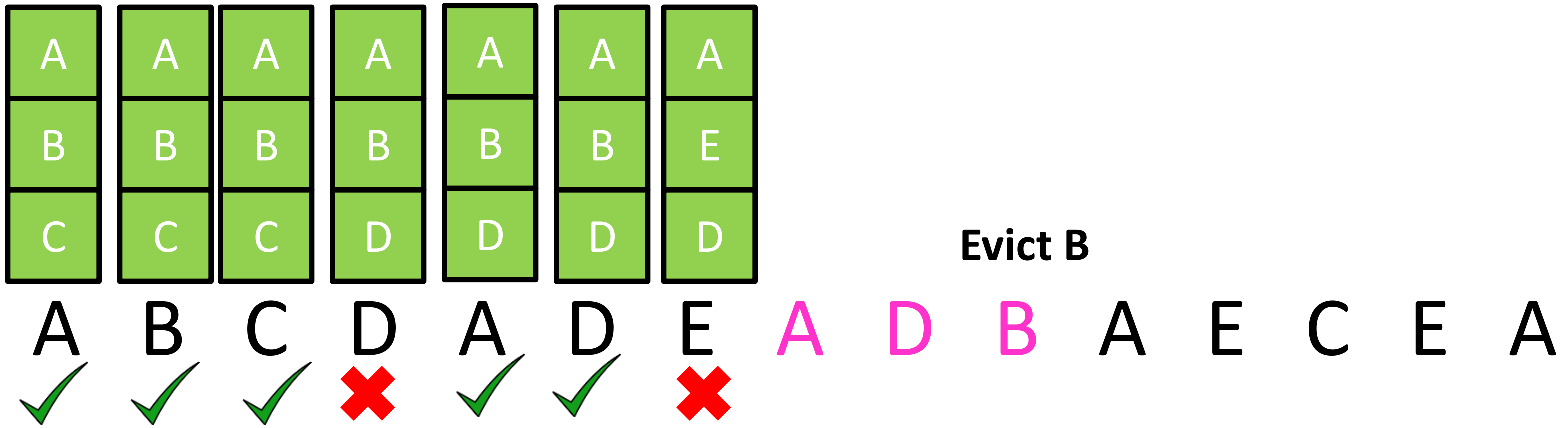
- Require Optimal Substructure
  - Solution to larger problem contains the solution to a smaller one
  - Only one subproblem to consider!
- Idea:
  1. Identify a greedy choice property
     - How to make a choice guaranteed to be included in some optimal solution
  2. Repeatedly apply the choice property until no subproblems remain

Greedy choice property

- Belady evict rule:
  - Evict the item accessed farthest in the future

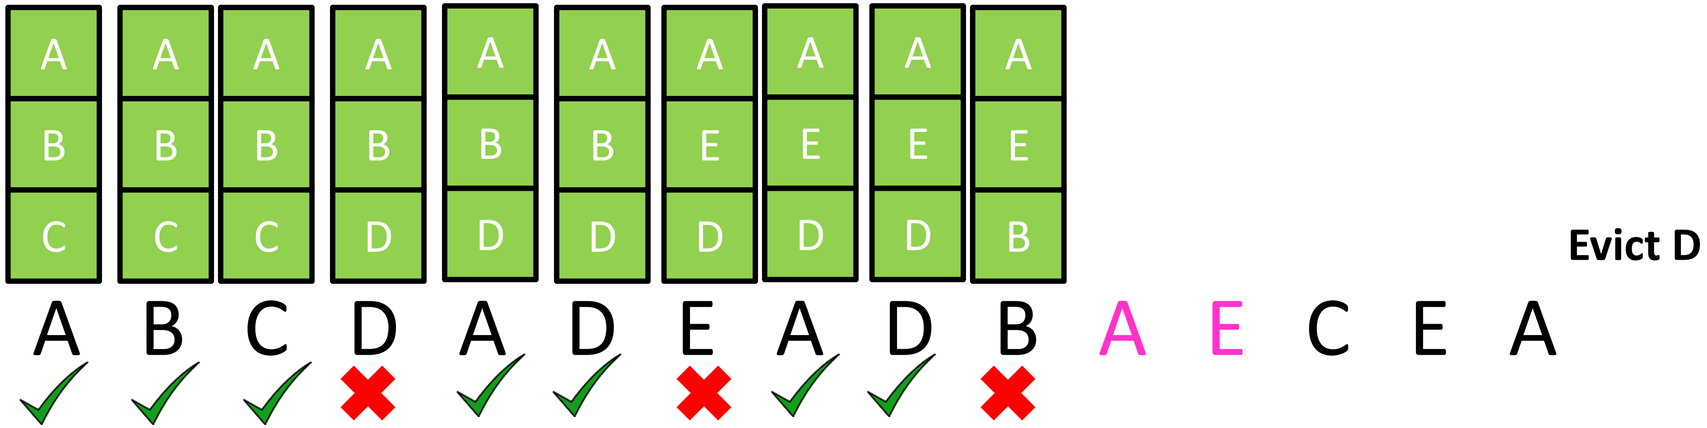
Greedy choice property

- Belady evict rule:
  - Evict the item accessed farthest in the future



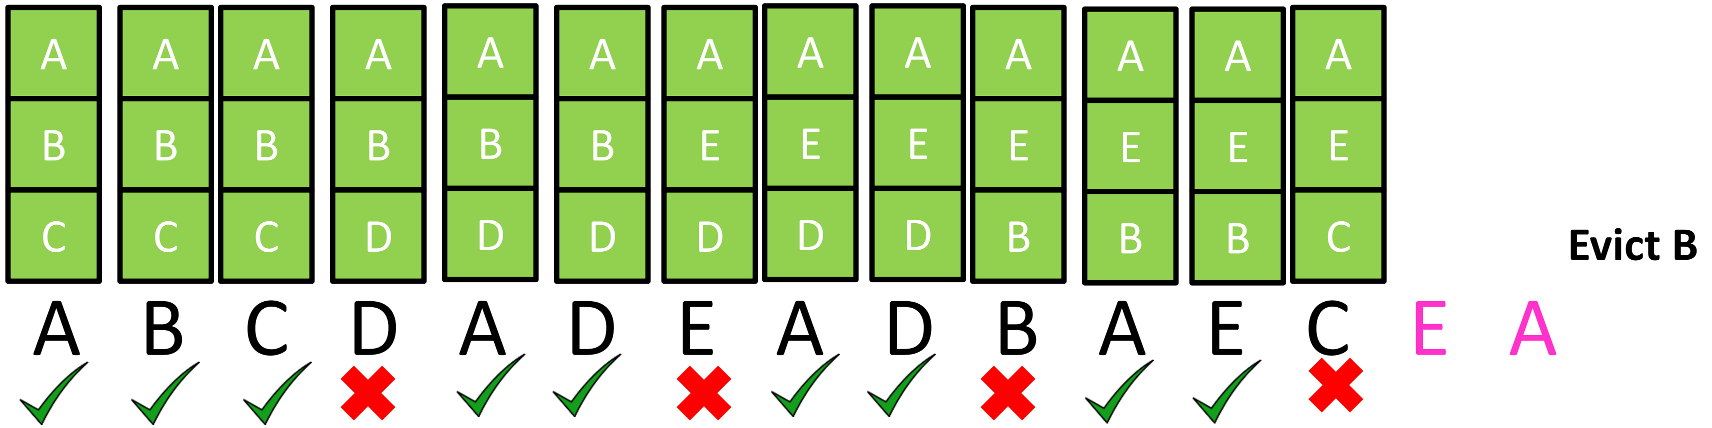
Greedy choice property

- Belady evict rule:
  - Evict the item accessed farthest in the future



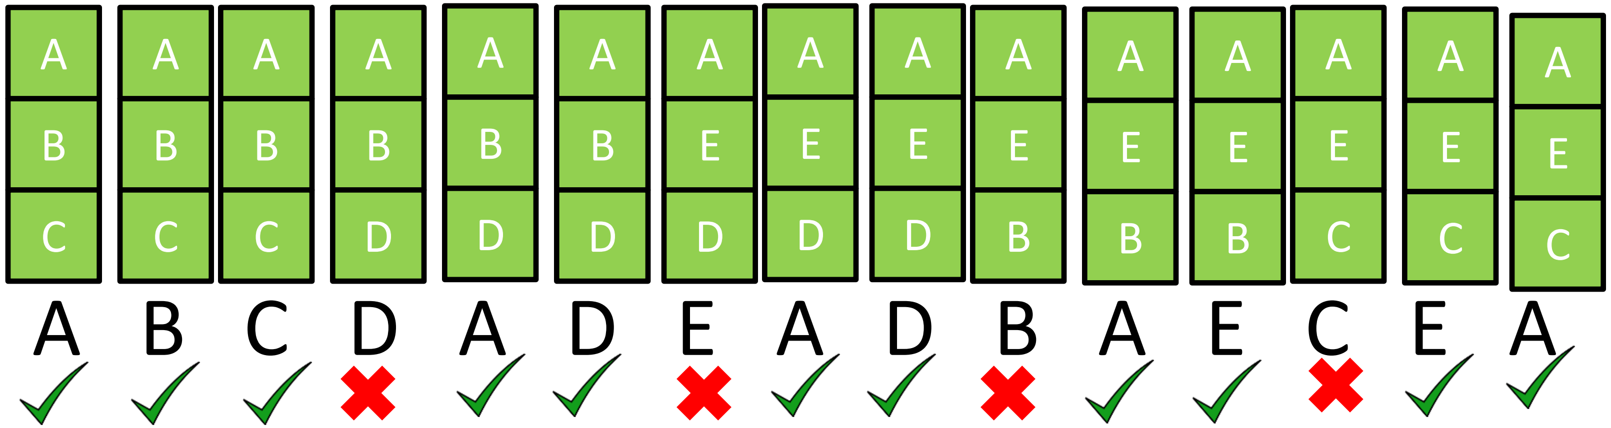
Greedy choice property

- Belady evict rule:
  - Evict the item accessed farthest in the future



Greedy choice property

- Belady evict rule:
  - Evict the item accessed farthest in the future



4 Cache Misses

Greedy Algorithms

- Require Optimal Substructure
  – Solution to larger problem contains the solution to a smaller one
  – Only one subproblem to consider!
- Idea:
  1. Identify a greedy choice property
     - How to make a choice guaranteed to be included in some optimal solution
  2. Repeatedly apply the choice property until no subproblems remain

Caching Greedy Algorithm

Initialize $cache$= first k accesses $O(k)$

For each $m_i \in M$: n times

if $m_i \in cache$: $O(k)$

print $cache$ $O(k)$

else:

$m =$ furthest-in-future from cache $O(kn)$

evict m, load m_i $O(1)$

print $cache$ $O(k)$

$O(kn^2)$

Exchange argument

- Shows correctness of a greedy algorithm
- Idea:
  - Show exchanging an item from an arbitrary optimal solution with your greedy choice makes the new solution no worse
  - How to show my sandwich is at least as good as yours:
    - Show: “I can remove any item from your sandwich, and it would be no worse by replacing it with the same item from my sandwich”

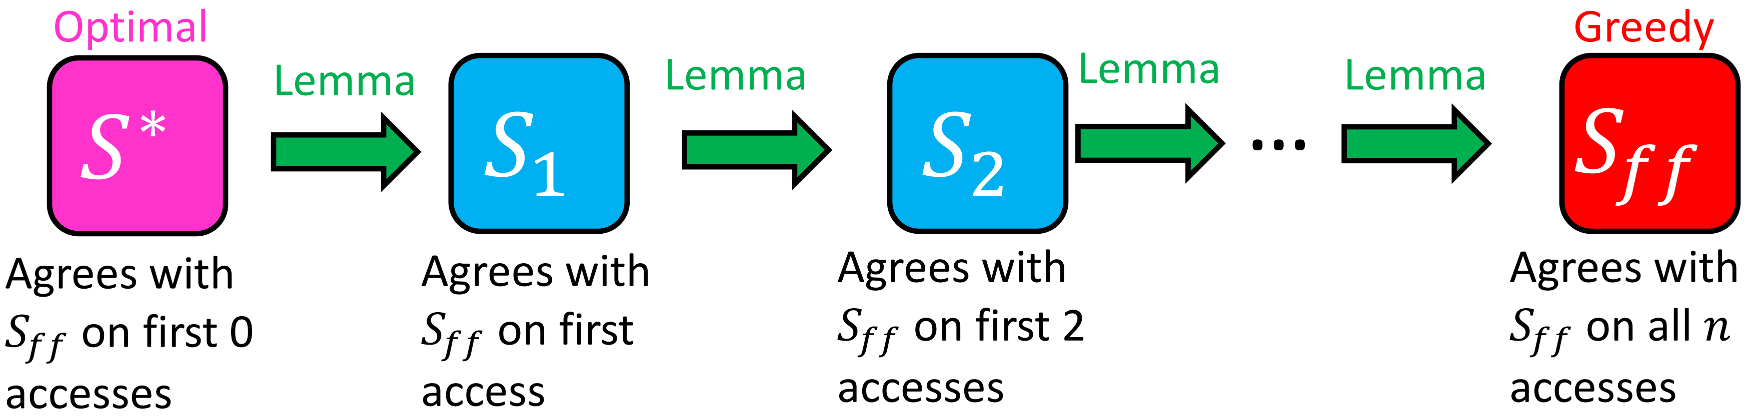
Belady Exchange Lemma

Let S_{ff} be the schedule chosen by our greedy algorithm

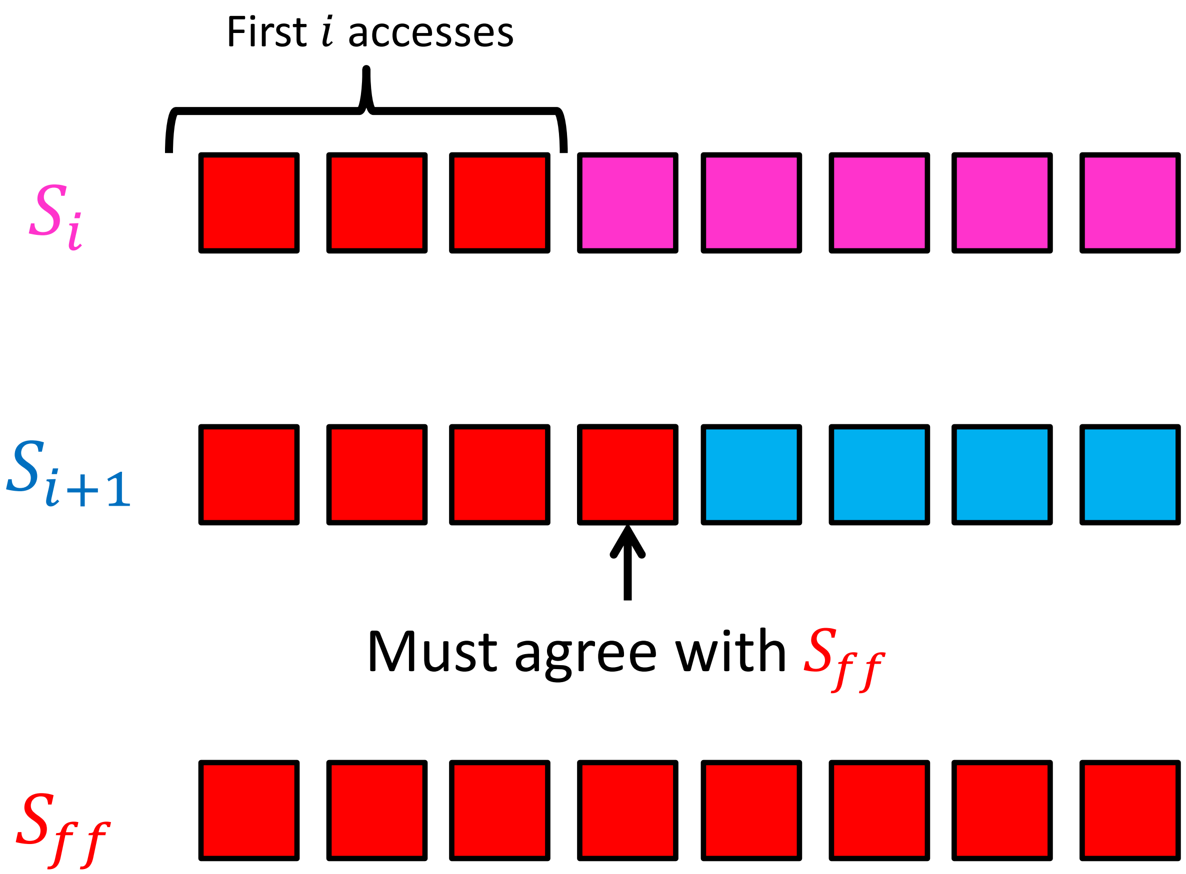
Let S_i be a schedule which agrees with S_{ff} for the first i memory accesses.

We will show: there is a schedule S_{i+1} which agrees with S_{ff} for the first $i+1$ memory accesses, and has no more misses than S_i

(i.e. $misses(S_{i+1}) \leq misses(S_i)$)



Belady Exchange Proof Idea

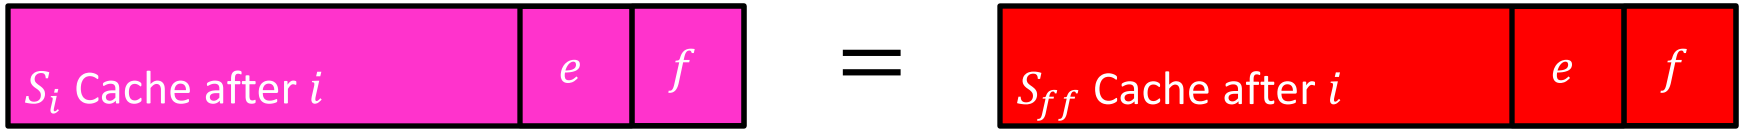


Need to fill in the rest of S_{i+1} to have no more misses than S_i

Proof of Lemma

Goal: find S_{i+1} s.t. $misses(S_{i+1}) \leq misses(S_i)$

Since S_i agrees with S_{ff} for the first i accesses, the state of the cache at access $i+1$ will be the same



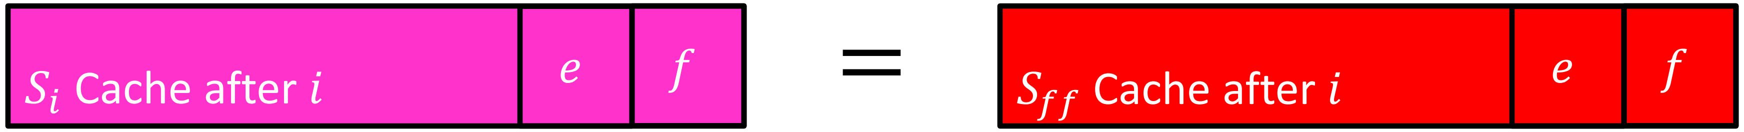
Consider access $m_{i+1} = d$

Case 1: if d is in the cache, then neither S_i nor S_{ff} evict from the cache, use the same cache for S_{i+1}

Proof of Lemma

Goal: find S_{i+1} s.t. $misses(S_{i+1}) \leq misses(S_i)$

Since S_i agrees with S_{ff} for the first i accesses, the state of the cache at access $i+1$ will be the same



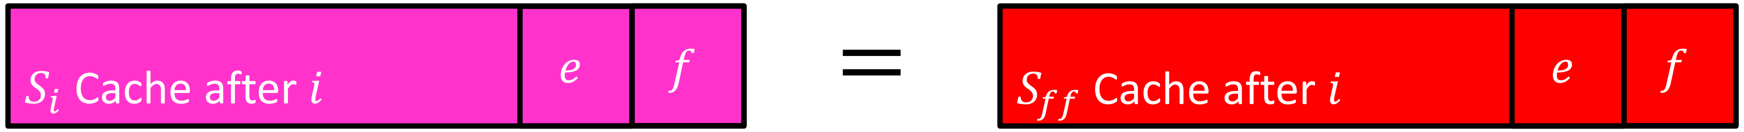
Consider access $m_{i+1} = d$

Case 2: if d isn't in the cache, and both S_i and S_{ff} evict f from the cache, evict f for d in S_{i+1}

Proof of Lemma

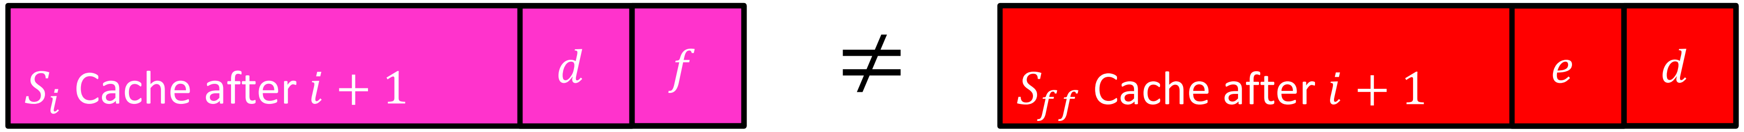
Goal: find S_{i+1} s.t. $misses(S_{i+1}) \leq misses(S_i)$

Since S_i agrees with S_{ff} for the first i accesses, the state of the cache at access $i+1$ will be the same

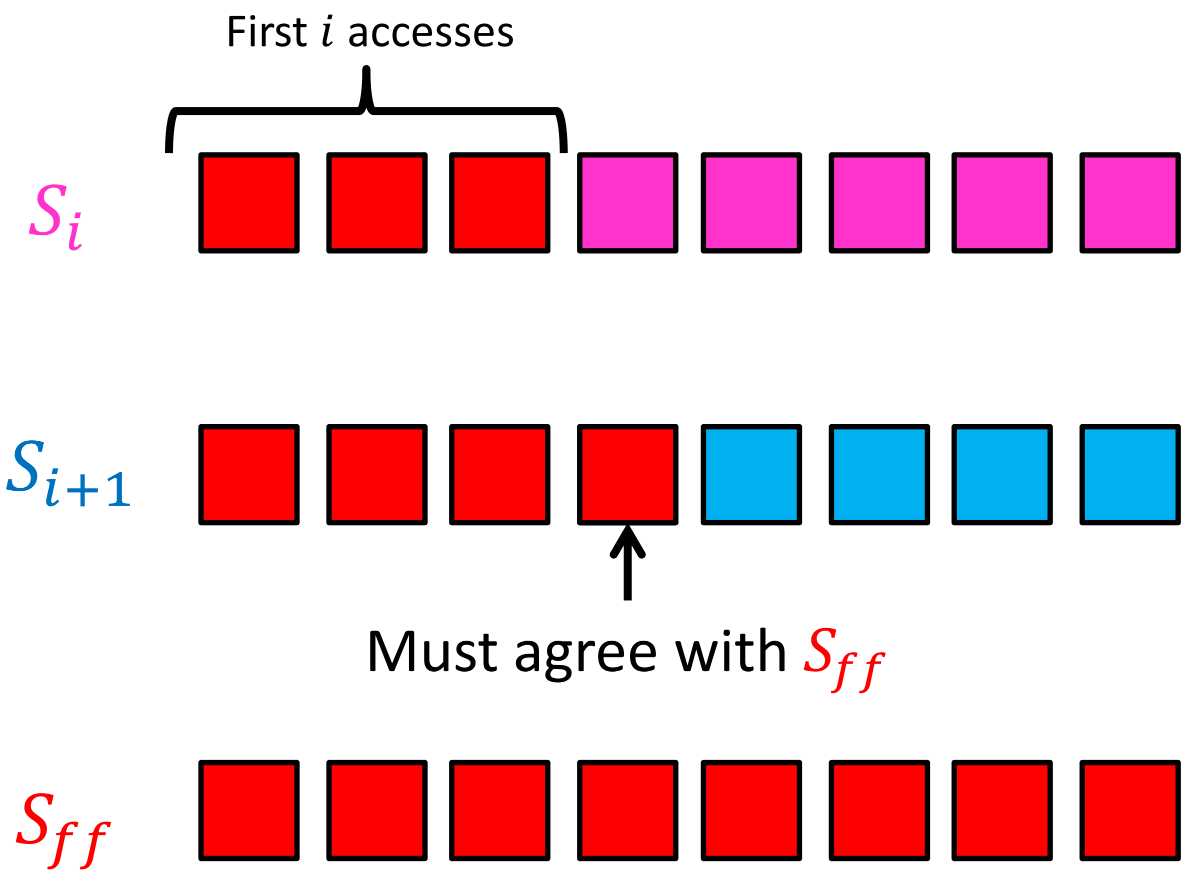


Consider access $m_{i+1} = d$

Case 3: if d isn't in the cache, S_i evicts e and S_{ff} evicts f from the cache



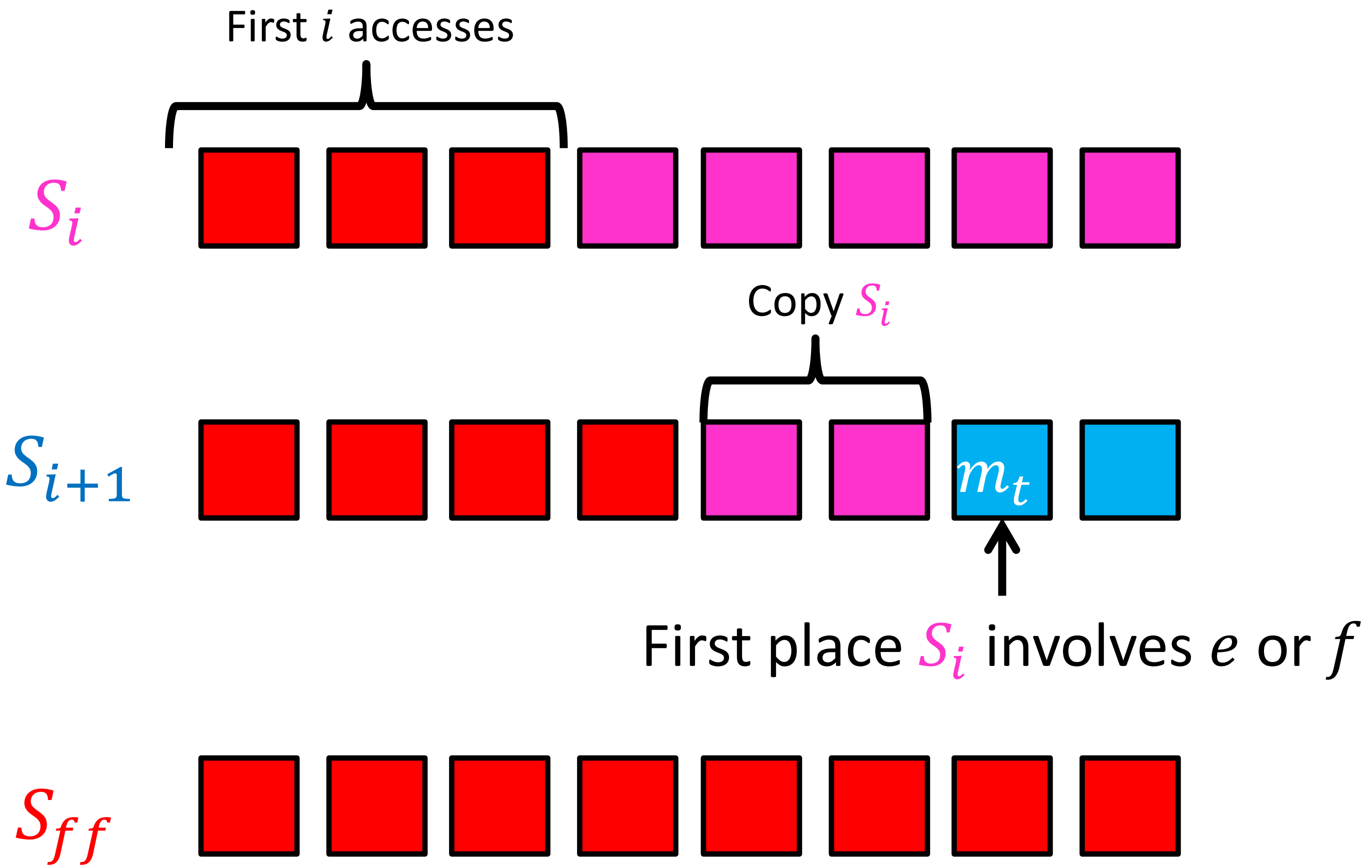
Case 3



Need to fill in the rest of S_{i+1} to have no more misses than S_i

Must agree with S_{ff}

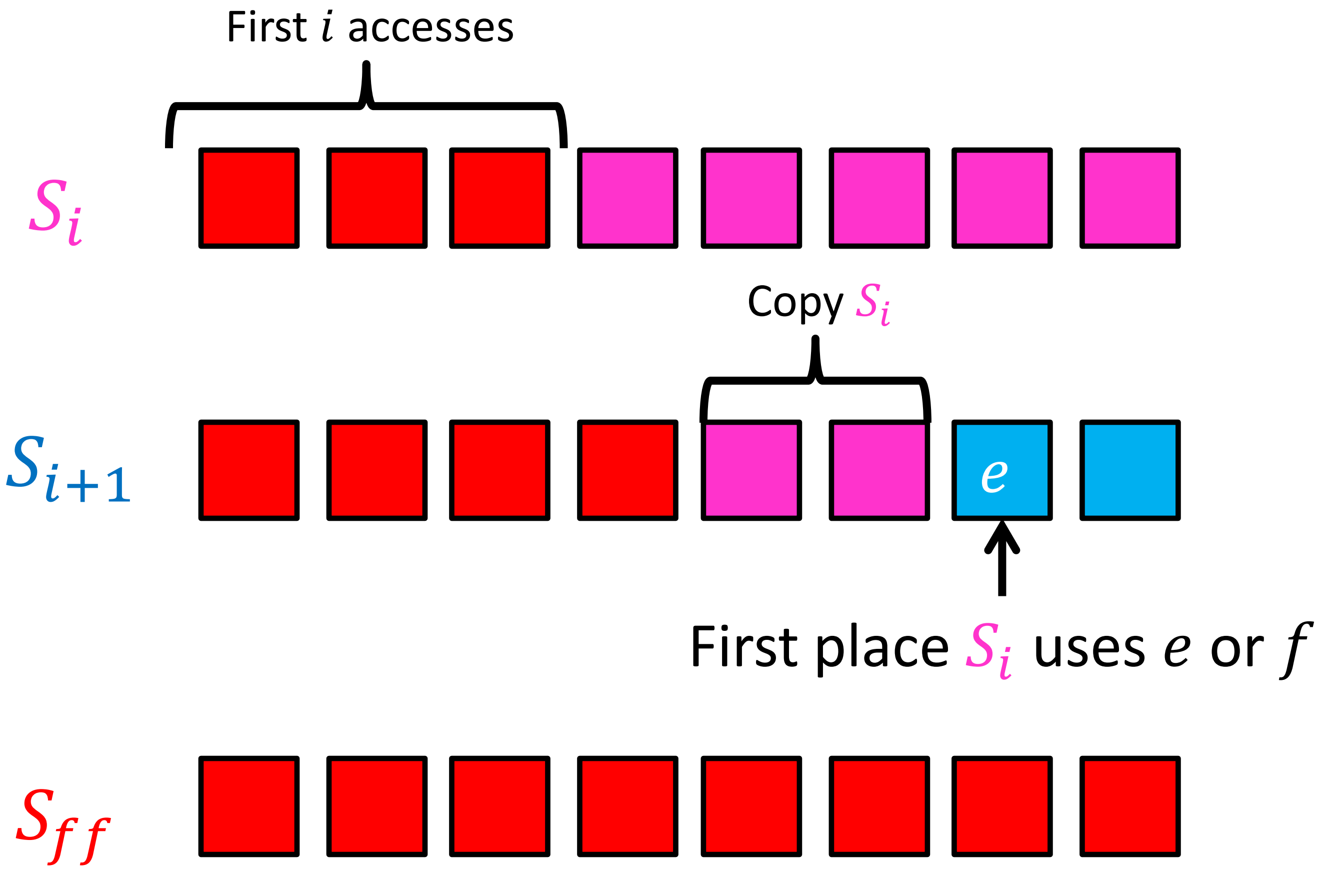
Case 3



m_t = the first access after $i+1$ in which S_i involveswith e or f

$\boldsymbol{m_t = e}$ or $\boldsymbol{m_t = f}$ or $\boldsymbol{m_t = x \neq e, f}$

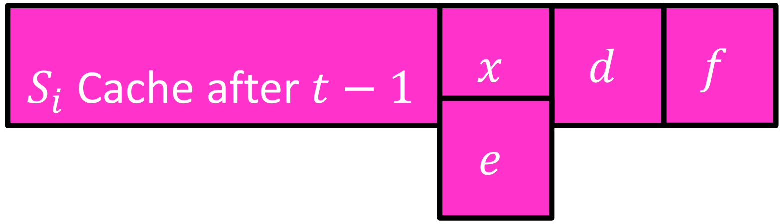
Case 3, $m_t = e$



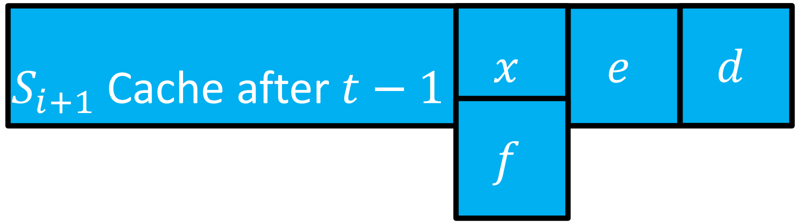
$m_t =$ the first access after $i+1$ in which S_i deals with e or f

Case 3, $m_t = e$

Goal: find S_{i+1} s.t. $misses(S_{i+1}) \leq misses(S_i)$



$\neq$



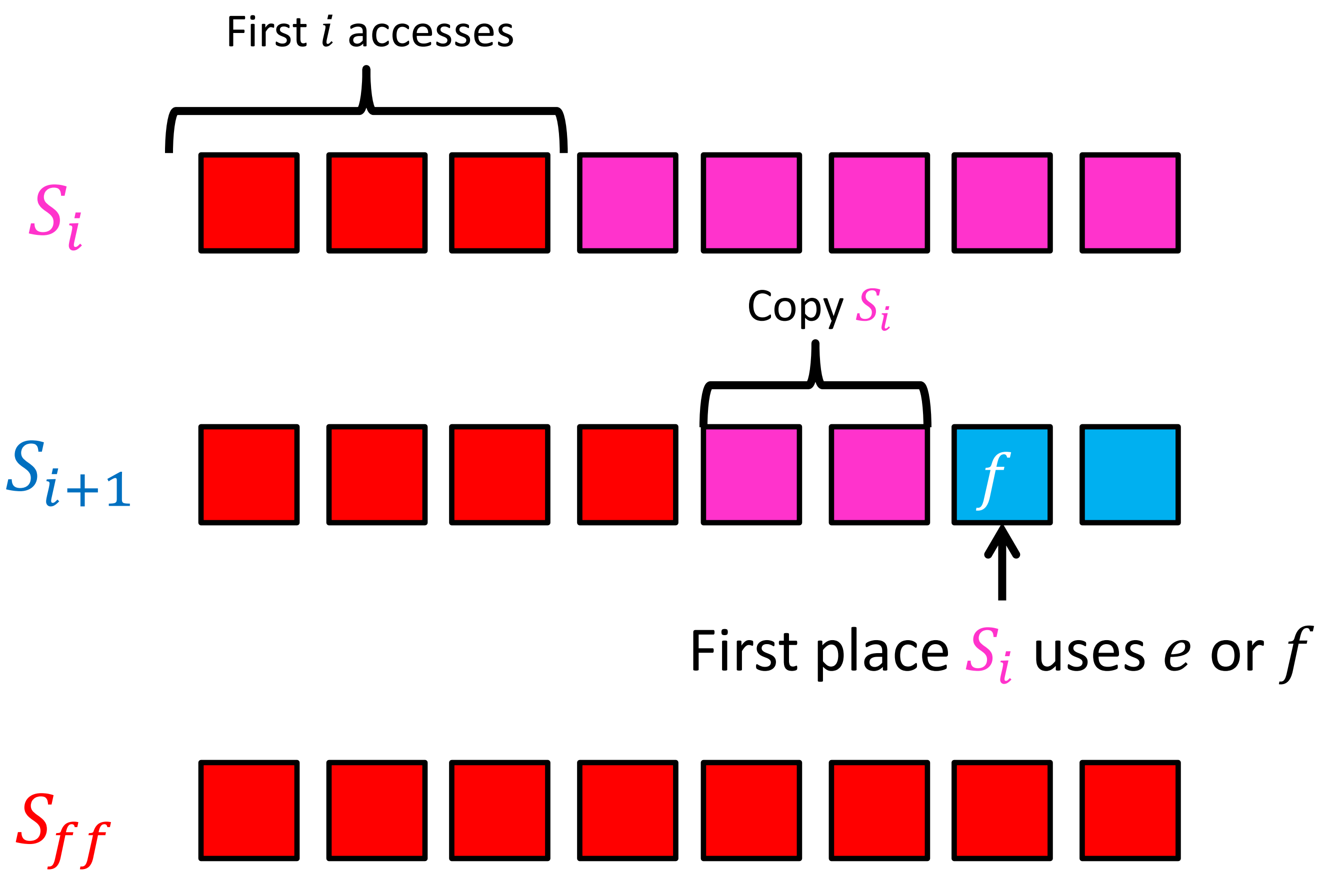
S_i must load e into the cache, assume it evicts x

S_{i+1} will load f into the cache, evicting x

The caches now match!

S_{i+1} behaved exactly the same as S_i between i and t, and has the same cache after t, therefore $misses(S_{i+1}) = misses(S_i)$

Case 3, $m_t = f$

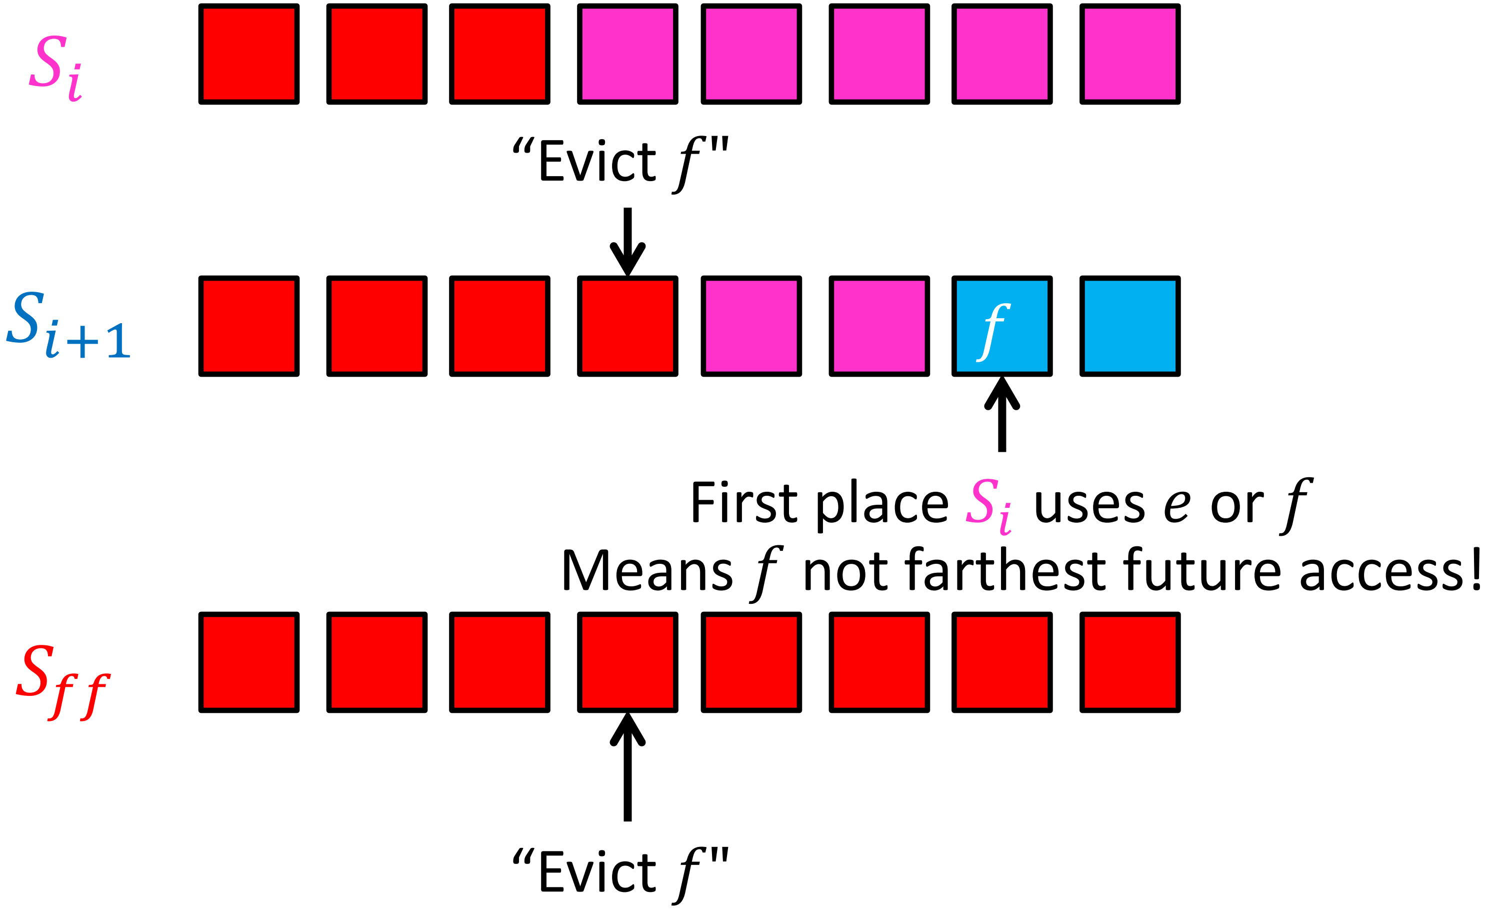


m_t = the first access after $i + 1$ in which S_i deals with e or f

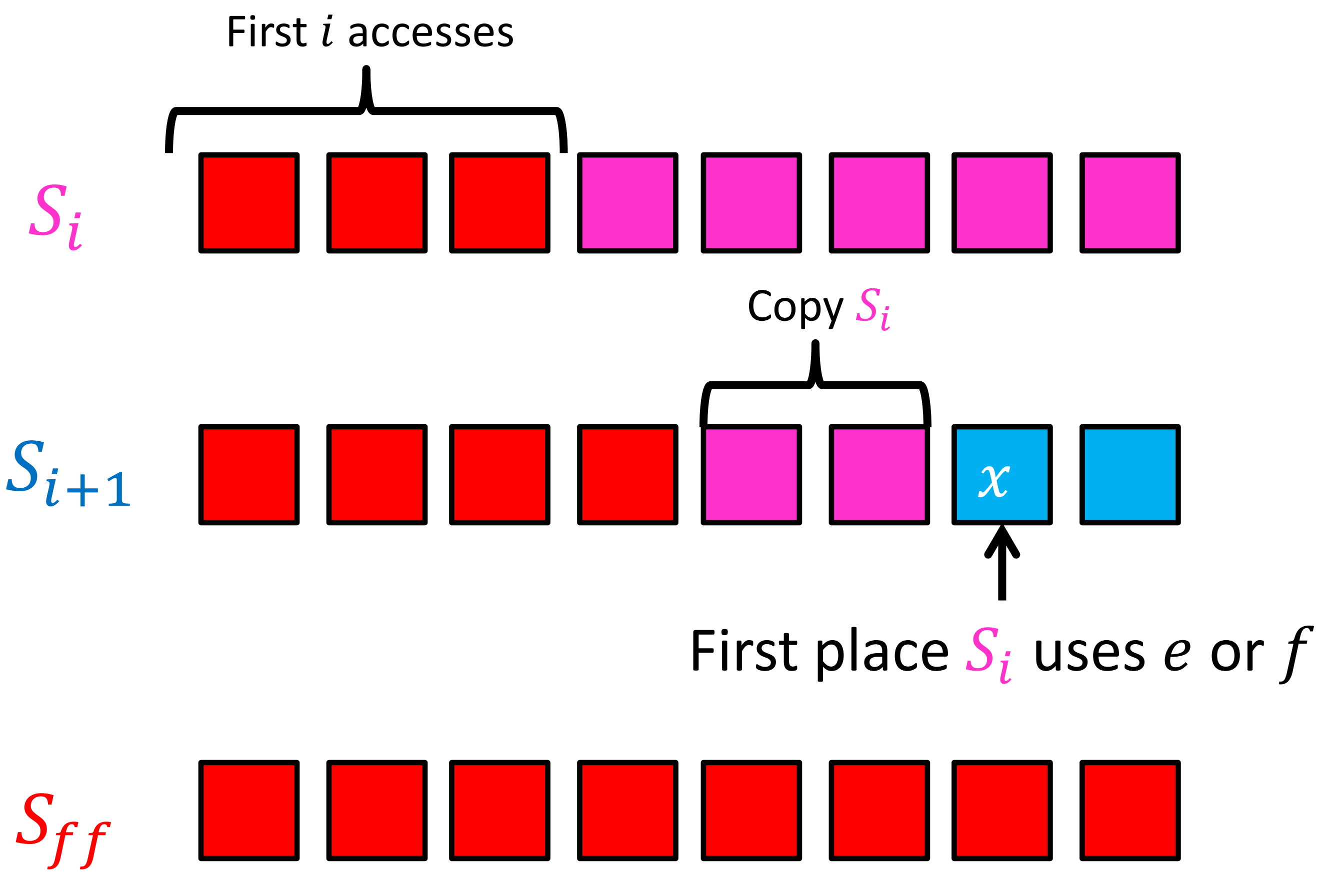
$\boldsymbol{m_t = e}$ or $\boldsymbol{m_t = f}$ or $\boldsymbol{m_t = x \neq e, f}$

Case 3, $m_t = f$

Cannot Happen!



Case 3, $m_t = x \neq e, f$

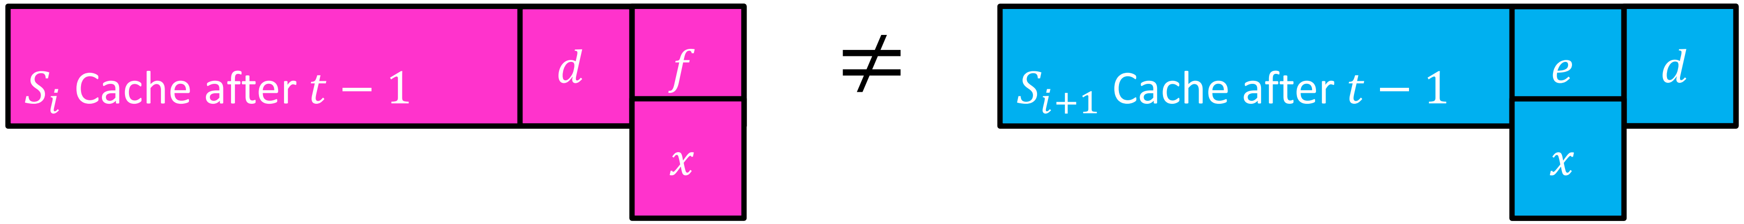


m_t = the first access after $i + 1$ in which S_i deals with e or f

$m_t = e$ or $m_t = f$ or $m_t = x \neq e, f$

Case 3, $m_t = x \neq e, f$

Goal: find S_{i+1} s.t. $misses(S_{i+1}) \leq misses(S_i)$



S_i loads x into the cache, it must be evicting f

S_{i+1} will load x into the cache, evicting e

The caches now match!

S_{i+1} behaved exactly the same as S_i between i and t, and has the same cache after t, therefore $misses(S_{i+1}) = misses(S_i)$
